Security and Atherization. · Confidentiality: Information not disclosed to non-authorized users - Integrity: Only authorized users should be allowed to modify data in expected Availability: Authorized users should not be denied access Security Policy / Operating System
Network
DBMS. "Who can access/modify what" Access central. Discretionary
. Users doit Mandatory. It can't be overniden by users Mondatory Access Control is DBMS dependent

DDA determines overal restrictions et users.
We do not cover it

Discretionary: Owner of an "object"

determines who can access/modify

it

Object can be relations, views, storedprocedures, user defined fractions, databases, etc.

Authorization Ids:

Every user is identified by one or more authorization is.

- ·userid
- · role: a user can belong to several roles · PUBLIC ; s special auth ID.

PRIVILEGES

- 1 SELECT can greny
- 2 INSERT insert into a relation
- 3) UPDATE update types in relation
 - . They can be further restricted to a set of attributes.

SELECT (name, addr)

allows to geny only these attributer.

INSERT (name, addr) allows to insert a

tiple but only to specify given attributes

(rest are set to default).

- a DELETE delete from relation
- (5) REFERENCES the hight to create a foreign Very constraint on a relation.

Say relation S has FK to relation R. User has INSERT on S but no priv. on R.

- Every insertion into S regumes a lookup into R

By attempting to insert user can figure if a value is present in R!!

Ultra secret table Invited (sid) with the sid of steents.

Johnny has no privilege on it. the can't read it

Johny creates a new relation

My Invited (sid) with Foreign Key

to Invited (sid)

Johny can now try to insert to My Invited every potential sid. If rejected, sid not in Invited.

For this reason, we need a special privilege to create Foreign Key constraints.

Why not simply require SELECT (sid) on Invited)?

It would be straighforward to gueny Invited.

REFERENCES only allows indirect look upr.

Important: REFERENCES is regined only on the table beign referenced, and only by the user areating the Foreign Key.

- · User Bob creates Invited
- · For user Johny to be able to create Foreign key from MyInvited to Invited, Johnny requires REFERENCES on Invited
- . To be able to have INSERT of UPDATE on My Fruited a user does not need REFERENCES on Invited.
- © USAGE. Applies to non-relation objects.

 Bight to use it

 Non relevant for our course.

1) TRIGGER. Right to add a trigger on a relation

A trigger is likely to require one or more privileges to work.

. User creating trigger must have Principles

. User executing trigger does not need them.

> trigger is executed under privileges of creator of trigger.

- (8) EXECUTE. Right to execute a certain funtion or stored procedure.
 - 9 UNDER. Right to define a subtype of a given type.

The creator of an DB element (table, view, UDF) is its owner.

- -Owner has all privileges on object -Owner (and dba) can give privileges to others.

Privilege Checking Process Any DB operation involves:

- . The database elements on which the operation is performed
- . The agent that causes the operation - can be a user or a process

-has a current authorization ID The operation is executed only if the current authorization is has all the provileges needed to perform the operation.

Example:

Assume table Streents (sid, sname), Courses (cid, chame) and Enrolled (sid, sid) Enrolled has FK references to both Stidents and Courses.

1) To create Enrolled we need REFERENCES in Students and Courses. We only use REFERENCES when we create a relation.

we need | SELECT |
INSERT |
DELETE update

On either relation!! REFERENCES only needed at creation.

3) DELETE FROM Enrolled WHERE sid = (SELECT sid FROM STUDENTS S WHERE S. name = 'Bob');

Minimum privileges required DELETE on Envolved

select on Enrolled (sid)

· We need to guery Enrolled to to find tople to delete! !.

SELECT on Statents (sid, sname)

4) UPDATE Students SET

sname = 'abc'

Min priv. required:

UPPATE Students (sname)

5) INSERT INTO Enrolled
UALUES (123', 1xyz')

Requires only INSERT on Enrolled.

Look-ups do not require SELECT on

Students nor Courses. They are allowed
be cause the FK constraints

6) INSERT INTO Streents (sid) VALUES ('392')

Regines only INSERT on Students (sid)

Now assume that FK constraints were created with ON DELETE CASCADE

7) DELETE FROM Students
WHERE sid = 1234';

If table Enrolled has one or more

tuple / for sid = '234'

We not ld require:

- DELETE ON straints

- SELECT ON Students

We do not need DECETE on Enrolled
